

Cross Reactants /potential reactants and cross-reactants

Cross reactivity of structurally similar substances can be a problem associated with immunoassay methods, which can result in false positive or negative results. Screening technologies are predominantly immunoassay techniques which have proven to be highly sensitive but are of limited specificity. Manufacturers will test for common substances that may interfere with results and list these on product package inserts. It is not possible however, to test for every compound. In addition, some compounds ingested in therapeutic doses may not cross-react, however when abused in “mega” doses may significantly influence urine immunoassay results.

Below are potential reactants and cross-reactants with most immunoassay methods. This list is to be used as a reference guide only and in no way is intended to be a comprehensive guide used for analysis.

List is not all inclusive. It is possible that other substances and/or factors not listed may interfere with the test and cause false positive results.

All positive results from an onsite drug testing product are presumptive and should always be screened at the laboratory for immunoassay results. An additional confirmatory method such as gas chromatography/mass spectrometry (GC/MS) is also recommended.
